In summary, it would seem that the relative contributions of electrostatics, dispersion, and direct interactions to the substituent effects seen in pi stacking interactions are highly dependent on geometry and experimental design.

A typical soil is about 50% solids (45% mineral and 5% organic matter), and 50% voids (or pores) of which half is occupied by water and half by gas. The percent soil mineral and organic content can be treated as a constant (in the short term), while the percent soil water and gas content is considered highly variable whereby a rise in one is simultaneously balanced by a reduction in the other.

Each kerogen type has a different origin and precursor, structure, and diagenetic signature upon thermal maturation. Thus, whether the OM being examined is kerogen, bitumen or pyrobitumen may control the process(es) involved in the development of organic pores, the timing of pore development, the character of the pores, and the associated network.

Terrestrial and Palustrine Plant Communities of Pennsylvania 2nd Edition represents the 3rd approximation of plant communities for Pennsylvania. Plant communities of Pennsylvania were first published in draft form by the Pennsylvania Natural Heritage Program in 1983 by Tom Smith with major revisions in 1991 and again with minor revisions in 1994.

It is! But really the exciting part is the MSR. Yes Thorium is exciting too because there's so much of it around. However

thorium itself is not fissile and must be converted to Uranium-233.
